NTI Python Training Instructor

The Problem

Cyber extortion is a serious threat. Victims face threats, private content exposure, and financial demands.

They struggle to organize evidence and don't know how severe their situation is. There's no structured way to manage case information.

Our Solution

AmaNet is an educational Python prototype that organizes the entire process into one structured workflow.

It helps victims effectively manage the entire case process, from initial registration to final report generation, in an organized manner.

Educational prototype only — no real report transmission.

Case Registration

Victim Information

Each case starts with victim information: name, phone number, and an auto-generated Case ID.

Case Type Selection

Users select a case type from options like Financial Blackmail, Photo Blackmail, Electronic Harassment, Identity Theft, or Other.

Data Storage

All collected data is securely stored in `cases.json` using Python OOP and JSON serialization for robust management.

Case Management

- Each case is assigned a unique Case ID automatically.
Case information is organized using Python classes and objects.
- Case data can be converted into dictionaries for structured storage.
- Cases are saved in a JSON file for persistent data storage.
- The system keeps important case details such as victim information, case type, creation date, and current status.

Risk Assessment

AmaNet asks 5 simple Yes/No questions to determine case severity:

Direct physical threat?

Private photos involved?

Repeated threats?

Personal information misused?

Financial demands made?

Each answer contributes a weighted score based on the level of risk.

Risk Levels

LOW

MEDIUM

HIGH

CRITICAL

This helps victims understand how serious their situation is and guides them toward appropriate action.

Evidence Collection

AmaNet supports multiple evidence types for thorough cyber extortion case management:

Screenshots

Messages

Files

Videos

Audio

Links

Other

Each evidence item is timestamped automatically, ensuring accuracy and integrity.

Users also record crucial extorter information: name, phone, and profile link. All evidence is organized and linked to the case.

Evidence Management

Every piece of evidence is stored with: type, description, file path .

The system uses Python lists and dictionaries to organize evidence. This structured approach ensures nothing is lost and everything is easily retrievable for the final report.

Location & Security Information

Users select their governorate from a list. AmaNet retrieves security directorate information: name, address, hotline, landline, and WhatsApp contact. This is prototype data only time routing. It helps victims know where to report locally.

Official Incident Report

AmaNet combines all information into one organized report:

Case Details

Victim Info

Extorter Info

Risk Score

Evidence Summary

Security Directorate Contact

The report is saved as Police_Report_[CaseID].txt. This is a simulated report for the prototype.

Safety Guidance

Don't Pay the Extorter

Resist demands, as this often leads to further extortion.

Don't Delete Evidence

Every piece of data is crucial for investigation.

Block Immediately

Prevent further communication from the extorter.

Keep All Messages

Archive every interaction for future reference.

Tell a Trusted Person

Seek support and guidance from someone you trust.

Emergency Hotline: 108

Contact authorities for immediate assistance.

AmaNet provides these safety tips at the end of the process to help victims protect themselves while their case is being handled.

Technologies & Libraries

Python Concepts

- 1 Python Basics
- 2 Functions
- 3 Object-Oriented Programming
- 4 Classes & Objects
- 5 Lists & Dictionaries
- 6 File Handling
- 7 JSON Serialization
- 8 f-strings

Libraries

`random` (generates Case IDs)

`datetime`

`json` (saves case data)

`tkinter` (GUI)

`arabic_reshaper` & `bidirectional` (Arabic text support)

Thank You 😊
